Sexual dimorphism in growth

Conclusions

The Von Bertalanffy's growth model (1938)

Bioenergetics grounds

$$\underbrace{\frac{dW(t)}{dt}}_{\text{Changes in individual weight}} = \underbrace{\eta \times (W(t))^d}_{\text{Energy assimilation}} - \underbrace{\kappa \times (W(t))^n}_{\text{Energy losses}}$$

Where η and κ are constants of anabolism and catabolism, respectively.

Hypotheses

1. Energy density is constant
2. Energy assimilation is proportional to surface areas ($d = 2/3$)
3. Energy loss is proportional to body weight ($n = 1$)

The Von Bertalanffy's growth model (1938)

Bioenergetics grounds

$$\underbrace{\frac{dW(t)}{dt}}_{\text{Changes in individual weight}} = \underbrace{\eta \times (W(t))^d}_{\text{Energy assimilation}} - \underbrace{\kappa \times (W(t))^n}_{\text{Energy losses}}$$

Where η and κ are constants of anabolism and catabolism, respectively.

Hypotheses

1. Energy density is constant
2. Energy assimilation is proportional to surface areas ($d = 2/3$)
3. Energy loss is proportional to body weight ($n = 1$)

Assumption of isometric growth: $W(t) = a \times L(t)^3$

Figure: $L(t) = L_{\infty} \times (1 - \exp(-K \times (t - t_0)))$. Growth for females *Lebigstes reticulatus* (von Bertalanffy & Müller 1949)

von Bertalanffy growth initially used for tropical tunas

(a) Yellowfin in the Atlantic (Le Guen & Sakagawa 1972)

(b) Bigeye in the eastern Pacific (Schaefer & Fuller 2006)

Conclusions

Tropical tunas question the use of VBGMs

| Region | Size | Rate | Data | Source |
|-------------|----------|--------------------------|-------------|--------------------------|
| E. Atlantic | 40-70 cm | 1.56 cm mo ⁻¹ | Catch & Tag | Fonteneau 1980 |
| E. Atlantic | 40-70 cm | 1.48 cm mo ⁻¹ | Tag | Bard 1984 |
| E. Atlantic | 40-70 cm | 1.62 cm mo ⁻¹ | Catch | Gascuel et al. 1992 |
| W. Atlantic | 40-70 cm | 1.62 cm mo ⁻¹ | Catch | Gaertner & Pagavino 1992 |
| W. Pacific | 30-50 cm | 1.3 cm mo ⁻¹ | Catch | Brouard et al. 1984 |

Table: Mean monthly growth rates estimated for different yellowfin populations derived from length-frequency and tagging data

Observations from the 3 oceans

Growth rates estimated for small yellowfin tuna stocks appear significantly lower than expected from a von Bertalanffy model

Methodological issues or bio-ecological reasons?

Potential sources of error

1. **Modal progression analysis** based on length-frequency data of the catch: Perhaps?
2. **Age reading of otoliths** due to interpretation (Cf. Sardenne et al.): Perhaps?
3. **Fish selection at-tagging** through pole and line gear: NO (Cf. Hallier et al.)
4. **Fish selection at-recovery** due to specific fishing grounds from recovery gears
5. **Fish selection at-recovery** due to size-based selectivity from recovery gears

Fish selection at-recovery due to size-based selectivity from recovery gears

Figure: Simulations suggest that a 2-stanza growth might result from size-based selectivity of the purse seine fishery (Kolody 2011)

Rationale

Simulation approaches have been conducted during IOTC working groups (Hampton 2008, Anganuzzi 2008, Kolody 2011) but they yielded contradictory results

Objectives

Develop a simulation framework modelling tuna growth estimation from mark-recapture experiments:

1. To investigate the effects of **individual variability** and **size-dependent natural mortality**,
2. To test the hypothesis that **size-based selectivity** of some fishing gears might modify our perception of the functional form of tuna growth
3. To explore the influence of denying **sexual dimorphism** on growth model outputs

No sexual dimorphism in growth

Sexual dimorphism in growth

Conclusions

Simulating a mark-recapture experiment

Principles

1. Fish tagged and released with age assumed known at-tagging
2. They grow over time following a von Bertalanffy growth model with individual variability
3. Natural mortality derived from stock assessment
4. At each time step: (i) they die naturally, or (ii) they are caught by the fishery with size-based selectivity, or (iii) they survive
5. VB and VB-logK models are fitted to the age-length data
6. Models are compared using loglikelihood ratios

No sexual dimorphism in growth

Sexual dimorphism in growth

Conclusions

Case study of the Indian Ocean yellowfin

Tagging

- ▶ 50,911 fishes tagged: 46,845 from the RTTP and 4,066 from small-scale tagging operations
- ▶ Size-frequency histograms-at-tagging similar to the IOTTP

Biology

- ▶ VB growth with $\mu_K=0.4 \text{ y}^{-1}$ and $\mu_{L_\infty}=160 \text{ cm}$
- ▶ Individual variability through normal distribution on L_∞ and K with standard deviation of 10 cm and 0.1 y^{-1} , respectively
- ▶ Size-based natural mortality

Recaptures

- ▶ Assumption of separability of gear-specific fishing mortality
- ▶ Fishing mortality constant over the period analysed: $F=0.2$
- ▶ Size-based selectivity constant over the period analysed

Figure: Size-based selectivity for purse seiners

Recaptures

- ▶ Assumption of separability of gear-specific fishing mortality
- ▶ Fishing mortality constant over the period analysed: $F=0.2$
- ▶ Size-based selectivity constant over the period analysed

Figure: Size-based selectivity for all fishing gears

Scenario runs

- ▶ Gear-specific size-based selectivity
- ▶ With and without sexual dimorphism in growth with sex-ratio at-tagging of 0.5:
 - Males: $\mu_{L\infty}=160$ cm and $\mu_K=0.4$
 - Females: $\mu_{L\infty}=140$ cm and $\mu_K=0.6$
- ▶ Sensitivity to levels of individual variability
- ▶ Sensitivity to natural mortality: U-shaped (Hampton 2000)

Sexual dimorphism in growth

Conclusions

Key points

- ▶ Size-based selectivity might result in biases in growth estimation from mark-recapture experiments
- ▶ Purse-seine selectivity does not result in biases in “unisex” growth due to the large size-range of fishes harvested
- ▶ Recaptures limited to longline or pole and line fishing would result in strong biases in growth
- ▶ The absence of small sized tunas in longline fisheries might result in apparent 2-stanza growth
- ▶ Simulating sexual dimorphism in growth (i) results in similar patterns in estimation bias and (ii) does not indicate the emergence of 2-stanza growth from gear selectivity

What eco-physiological factors might explain the 2 stanzas?

Changes in metabolism

- ▶ For yellowfin, shift in growth at about 73 cm (± 7 cm) seems to match with period of acquisition of sexual maturity (Zudaire et al. 2010)
- ▶ Reduction in energy costs linked to change in aggregative behaviour and associated decrease in inter-specific competition
- ▶ Development of swim bladder, subcutaneous heat exchangers, deep red muscle, ram jet ventilation and anal and pectoral fins and associated reduction in energy costs as well as changes in utilisation of the vertical habitat

What eco-physiological factors might explain the 2 stanzas?

- ▶ Reduction in energy costs linked to change in aggregative behaviour and associated decrease in inter-specific competition
- ▶ Development of swim bladder, subcutaneous heat exchangers, deep red muscle, ram jet ventilation and anal and pectoral fins and associated reduction in energy costs as well as changes in utilisation of the vertical habitat

Going back to von Bertalanffy's studies

Figure: Growth of the albino rat with shift in mechanisms of energy allocation at maturity: 2 growth cycles must be distinguished (von Bertalanffy 1941)

What we call growth of even a simple organism is a tremendously complex phenomenon from the biochemical, physiological, cytological, and morphological viewpoints

Ludwig von Bertalanffy, 1957

The VB model is nested in the VB-logK model

Assumption of lognormal distribution of observed sizes

$$\log l_i^* \sim \mathcal{N}(\log L_{VB}(t_i|\theta_{VB}) - \sigma_2^2/2, \sigma_1^2),$$

$$\log l_i^* \sim \mathcal{N}(\log L_{VB \log K}(t_i|\theta_{VB \log K}) - \sigma_2^2/2, \sigma_2^2).$$

On obtient donc deux vraisemblances lognormales $L_{VB}(D|\theta_{VB})$ et $L_{VB \log K}(D|\theta_{VB \log K})$ où D indique les données

$$R = 2 \log \frac{L_{VB \log K}(\hat{\theta}_{VB \log K})}{L_{VB}(\hat{\theta}_{VB})} \sim \frac{1}{2} \delta_0 + \frac{1}{2} \chi_1^2$$
