Review of Japanese longline fishery and its albacore catch in the Indian Ocean

by Takayuki Matsumoto

National Research Institute of Far Seas Fisheries, 7-1, Orido 5-chome, Shimizu, Shizuoka, 424-8633, Japan

Summary

Status of effort, albacore catch and CPUE was summarized for Japanese longline fishery operating in the Indian Ocean including recent trends. Japanese longline vessels had been targeting albacore until late 1960s, albacore became non-target after that, but it has become one of target species in recent years. Fishing effort fluctuated and it sharply decreased in recent years due to the effects of piracy activities. Albacore catch was high in 1960s, sharply decreased in 1970s, and then gradually increased with fluctuation. In the early period, the effort was deployed mainly in the tropical area, and then expanded to the south. Fishing effort in the northwestern part (around Somalia) sharply decreased after 2009 due to piracy activities. During 1960s albacore was main component of the catch in the western part between 10°S and 35°S, and is recently main component in the southern part including west off Australia and around Madagascar.

1. Introduction

There are two kinds of Japanese tuna fishery in the Indian Ocean, i.e. longline and purse seine fisheries. Of those, only the longline fishery has caught albacore. The longline fishery commenced in 1952 in the eastern equatorial waters in the Indian Ocean. The fishing effort of the longline first expanded westward, and then southward. In the late 1960s, the effort covered entire fishing ground of the longline in the Indian Ocean. The annual amount of the effort has changed since the late 1960s. And also annual albacore catch have considerably changed, ranging from 400 t to 18,000 t (Table 1, Fig. 1), as well as catches of other tunas. Those changes were mainly due to the change of targeting as seen in the other Oceans.

In this document, historical and spatial changes of albacore catch, CPUE and the fishing effort were described in conjunction with the catches of the other tunas and tuna-like species. These will be useful for considering CPUE standardization for albacore caught by Japanese longline fishery.

2. Data source

In order to count number of hooks and catches in number of tunas and billfishes, basic data used here is the logbook data that have been compiled at National Research Institute of Far Seas Fisheries (NRIFSF) based on the logbook mandatory submitted by the fishermen of the longline vessels larger than 20 gross ton (GRT). The data are so-called "raised" data, which is aggregated by month and 5°x5° block, and then expanded with coverage rate of the logbook. The basic data is available for 1952-2015. Data for 2015 are preliminary. To count fishing effort by number of hooks per basket, logbook data aggregated by month, number of hooks per basket and 5°x5° block, which is not raised, were used. As for albacore catch in weight by area, IOTC database as of June 2015 was used.

3. Trend of catch and effort

Table 2 and Fig. 2a indicate that after the beginning of the exploitation by longline fishery in the Indian Ocean, annual fishing effort increased until 1967 and then fluctuated ranging from 40% to 99% of the peak year until 2009. However, fishing effort has been decreasing since 2007, and in 2015 (preliminary) it decreased to

about 22% of the peak value. Main reason of the decrease in recent years is the effects of piracy activities in the western Indian Ocean (around Somalia). The albacore catch (in number) peaked (1,010 thousands fish) in 1962 and 1964, then sharply decreased to 32 thousands fish in 1978 and 1979, corresponding to 3% of the level in peaked year, and then gradually increased with fluctuation. The catch in 2006 was 481 thousand fish, which corresponds to 48% of peak value and was highest since 1970. After that the catch decreased again until 2009, and the trend was not clear after that. Following is the description for the temporal and spatial changes of the catch and the effort including detailed description in recent years.

Fig. 3 shows historical change in the proportion of fishing effort (number of hooks) by each category of number of hooks per basket (HPB). In the all Indian Ocean, 4-7 HPB was dominant until early 1990s, but it sharply decreased around mid-1990s. The effort for 8-11 HPB was main component during early 2000s, but the proportion of 12-15 and 16-21 increased after that. In the tropical area, 16-21 HPB has been main component since mid-1990s, but 8-11 and/or 12-15 HPB are dominant in the temperate area.

Fig. 4-Fig. 6 show geographical distribution of fishing effort (number of hooks), albacore catch and CPUE by each decade, respectively. In the 1950s, when the effort increased (Fig. 2a), the effort was deployed mainly in the region north of 15°S. The main component of the catch was yellowfin tuna in this period (Fig. 2c).

Following this period, the effort continued to increase up to 130 million hooks until the late 1960s (Fig. 2a). In this period, the total catch of four species of tunas, i.e., yellowfin, albacore, southern bluefin and bigeye tunas was historical highest, and species-specific catches were also the highest for yellowfin, albacore and bluefin tunas (Fig. 2c). Of the four species, yellowfin tuna was the most dominant catch in this period, to the lesser extent, albacore and southern bluefin tuna. Also the catch of bigeye tuna in this period increased compared to the 1950s. In this period, fishing ground of this fishery expanded to southward, in the west side and the east side of the Indian Ocean, excluding the southern central of the Indian Ocean. Albacore catch was high in the region between 10°S and 35°S, which corresponds to the region of South Equatorial Current (Sub-tropical waters). The CPUE of albacore was also high in the west side of the region, eventually increasing overall CPUE of entire Indian Ocean (Fig. 2b), but in the east side the CPUE was lower compared with west side. In the west side of this region, main component of the catch was albacore (Fig. 7), on the other hand, southern bluefin tuna was the largest component in the east area.

In the period from the late 1960s to the late 1970s, the effort decreased to about 60 million hooks, about 50% of the peak year (Fig. 2a). In this period, each catch of yellowfin and albacore drastically decreased compared to that in the previous period (Fig. 2c). This decrease was due to withdrawing in the effort from the fishing ground ranging from 10°S to 35°S.

In the period from the late 1970s to the mid 1980s, the effort increased again and reached to 130 million hooks (Fig. 2a), the same level as the previous peak in the 1960s. This increase was seen in the regions off Somalia and the south of 35°S, targeting bigeye tuna and high quality (=oily) southern bluefin tuna, respectively.

In the period from the mid 1980s to the early 1990s, the effort decreased again (Fig. 2a). This decrease was due to the decrease of the effort in the region south of 35°S, corresponding to the fishing ground for southern bluefin tuna, by introduction of the TAC for southern bluefin tuna in 1986.

In the period from the early to late1990s the effort increased (Fig. 2a). The increase was seen in the regions off west coast of Australia probably targeting bigeye tuna, and south of Madagascar Island where yellowfin, albacore and bigeye were mainly caught (Fig. 7). In those region albacore was substantially caught, and this

contributes to the increase of total catch in the period (Fig. 2a).

In the period of 2000s the effort kept high until 2007, sharply decreased until 2012, and kept in a low level after that (Fig. 2a). The decrease has been seen especially in the regions off Somalia since 2010 (Fig. 8, Fig. 11). This is due to the effect of piracy activities in this area as mentioned above. As a result, the proportion of catch and effort in the area south of 25°S increased, where catch rate of albacore was higher. Also, increase of CPUE in the area west off Australia was observed during 2006-2007. These may have caused increase in albacore CPUE (Fig. 2b). In the area west off Australia, the proportion of albacore in the entire catch also increased during 2005-2007, and kept high thereafter (Fig. 11). As mentioned above, since the late 1960s, the longline fishery had been running without targeting albacore, and the effort had not been deployed in the region where albacore is abundant in general. Eventually, albacore had been caught only as a bycatch with southern bluefin tuna or bigeye tuna, to lesser extent with yellowfin tuna. In recent years, however, due to decreased quota of southern bluefin tuna and enhanced market value of albacore for sashimi products, more Japanese longline vessels are targeting albacore especially in the west off Australia. Also, recent situation of the change in the proportion of effort by area due to piracy activities seems to be unusual.

Historically, albacore was mainly caught in the southeastern and southwestern part (temperate and subtropical areas) of Indian Ocean. It seems that albacore was consistently caught in the southwestern part (around and south of Madagascar), and the catch became higher in the southwestern part (east off Australia) in recent years.

Table 1. Albacore catch in weight (t) caught by Japanese longline fishery. Western: FAO area No. 51 (mostly west of 80°E), eastern: FAO area No. 57 (mostly east of 80°E). Data source: IOTC database.
