## **1. Introduction**

French purse seiners operate in the Indian Ocean target yellowfin (*Thunnus albacares*), skipjack (*Katsuwonus pelamis*), and bigeye tuna (*Thunnus obesus*) through two major fishing modes : floating object-associated schools (FOB) and free-swimming schools (FSC) that result in different species and size compositions of the catches. Statistical data for the French purse seine (PS) fishing fleet have been collected by the ‘Institut de Recherche pour le Développement’ (IRD) in collaboration with the ‘Seychelles Fishing Authority’ (SFA) since the arrival of the first purse seiners in the Indian Ocean in the early 1980s. The French PS fleet activities are described through a suite of fishery indicators that provide information on fishing capacity, effort, catch, and catch rates for the tropical tuna species (skyjack, yellowfin and bigeye) targeted, with a particular focus on the year 2016.

## **2. Material and methods**

### **2.1 Data collection**

The data presented in this paper come from the collection of all logbooks and landing reports done in collaboration with the fishing companies. French purse seine logbooks are similar between companies and follow the standards defined by the Indian Ocean Tuna Commission (IOTC) following resolutions 15/01 ”On the recording of catch and effort data by fishing vessels in the IOTC area of competence” and 15/02 ”Mandatory statistical reporting requirements for IOTC Contracting Parties and Cooperating Non-Contracting Parties (CPCs)”. They include information on the position, date, fishing activities (route, fishing set, fishing mode and operation related to FOB), and environmental conditions associated with each activity (e.g. sea surface temperature, speed and direction of the wind).

### **2.2 Data processing**

The current sampling protocol, strata, and algorithms used for the logbook data processing were established during the European project ’Analyse du schéma d’échantillonnage multispecifique des thonidés tropicaux’ (Pallares and Hallier 1997).

Overall, the data processing aims to adjust the tropical tuna catch to the landings and estimate the size and species composition of the catch based on large sampling areas, fishing mode, and quarter (Pallares and Petit 1998). The estimation of the size and species composition relies on the merging of all size samples collected aboard European and associated flags purse seiners. Consequently, the size structure of the catches is given for the whole European fishery in a companion paper (Chassot et al. 2014b). Fishing time is computed from logbook information and by considering that purse seiners are only fishing during daytime, i.e. 13 hours a day on average in the Indian Ocean. Searching time was computed by subtracting the time spent for setting the gear from the fishing time. The time spent for setting the gear was estimated by regressions linking duration and size of sets, from at sea observations made by scientific observers. The spatial distribution of the effort was estimated by evenly allocating the fishing/searching time to the position(s) of fishing sets on a daily basis.

### **3. Fishing capacity and effort**

#### **3.1 Fishing fleet**

In 2016, the French fleet was composed of 1 supply vessel and 12 fishing vessels of capacity >800 t that corresponded to an overall carrying capacity 11,800 t (Fig. 1 and Table 1). The total number of active vessels has shown a decreasing trend over time, from a maximum of 26 in 1985 to a minimum of about 13 in the recent years, with a notable increase observed during 2006-2009 (Fig. 1). Meanwhile, the individual purse seiner carrying capacity has increased, which resulted in the overall capacity of the fleet to remain fairly constant during 1984-2016, on average of 14,000 t. The exceptional increase in the number of vessels and associated capacity during 2006-2008 was due to the arrival of several purse seiners from the atlantic ocean. This could be mainly explained by the high catch rates observed in the indian ocean during 2003-2005 that were twice those observed in the atlantic ocean. Lower catch rates which became very similar between oceans during 2006-2008, combined with piracy threat may have implied a reallocation of the purse seine effort in the atlantic ocean from 2009 (Chassot et al. 2010).

#### **3.2 Fishing effort**

The total nominal fishing effort, expressed in fishing and searching days, showed an overall decreasing trend over time during 1984-2016, similar to the number of vessels, with the notable major increase during 2006-2008 (Fig. 2 and Table 2). In recent years, the effort has shown an increase of more than 20% between 2010 and 2014. Then, the effort decreased by 9% due to the departure of 1 vessel to the Italian flag. In 2016, the total nominal effort was 3508 active days at sea, 2571 searching days and 3153 fishing days. The fishing grounds were located in the western part of the indian ocean in 2016, ranging from 15°S in the Mozambique Channel to a maximum of about 8°N, at the latitude of the horn of Africa, and from 40°E along the coasts of Mozambique and Tanzania, to 70°E (Fig. 3). While the extent of the fleet fishing grounds where some effort was exerted has decreased since 2008 from a maximum of about 400 to less than 300 squares of 1° latitude and longitude, it increased in 2016 to reach 450 squares (Fig. 4 and Table 3).

#### **3.3 Fishing sets**

The total annual number of fishing sets has remained stable during 2002-2016 at about 2,800, with 7% of the sets being successful during this period (Fig. 5 and Table 4). In 2016, two thirds of all sets made by the French purse seine fleet, i.e. 2000, were achieved on floating object (FOB) associated schools. The proportion of success increased from 85% in 2012 to 94% in 2016.

## **4. Fisheries production**

### ***4.1 Fishery landings***

In 2016, the total landings were 68419 t with a increase of 25% compared to 2015 (Fig. 6 and Table 5). The specific composition in 2016 was 49.3%, 45.1%, 5% and 0.6% yellowfin, skipjack, bigeye and other species respectively. Catch on FOBs increased by 54% in 2016 to reach more than 49,000 t (Fig. 7a and Table 6). The proportion of catches associated with FOBs has strongly increased from about 47% in 2005 to 72% in 2016.

### ***4.2 Catch rates***

The total number of positive sets per searching day (cumulating both fishing modes) has shown an increasing from 0.75 in 1981 to 1.43 in 2005. Since then, it has been decreasing to reach a low value <0.8 in 2014, i.e. lower than the levels observed during the El Niño event of 1997-1998 (Table 8). In 2016, the decreasing trend stopped at a value of 1.05 instead of 0.85. This increase is mainly due to the catch rates on FOBs with a higher value of 38%. During the same period, this increase was only of 6% on FSC.

For the number of sets per searching day on FSC, the increase is only 6% between 2015 and 2016.

The total catch per positive set on FOBs decreased from high values (average of more than 36 t per set) during 1999-2006 to an average of 27 t per set during 2007-2015 (Fig. 11c and Table 10). SKJ catch per positive set strongly decreased from maximum values of more than 27 t in 2002 to less than 13 t in 2012-2015. Meanwhile, YFT catch per positive set showed strong interannual variations during 1991-2015 with an overall increasing trend.

The catch per positive set on FSC has shown an increase in recent years, from 32.3 t in 2009 to more than 43 t in 2015 (Fig. 11c and Table 9). Values of YFT catch per positive set averaged around 39.7 t during 2010-2015.

The year 2016 does not follow the trend of the previous years with a 14% increase in catch per positive set on FOBs and 15% on FSC. It will be necessary to analyze next year's values to hypothesize a trend.

**Acknowledgments.** We thank ORTHONGEL, fishing companies, scientific observers, and all past and current personnel for helpful assistance in data collection and management. Sampling operations in Victoria were conducted in 2016 by J Esparon, A Stephen and R Rose. Data entry was assured by M Adeline and B Jean. Data processing of tuna fisheries data was conducted through close collaboration with SFA and IEO. This work was financed by the European Data Collection Framework (DCF, Reg 199/2008 and 665/2008) and the French ‘Direction des Pêches Maritimes et de l’Aquaculture’ (DPMA).

## 5. Figures

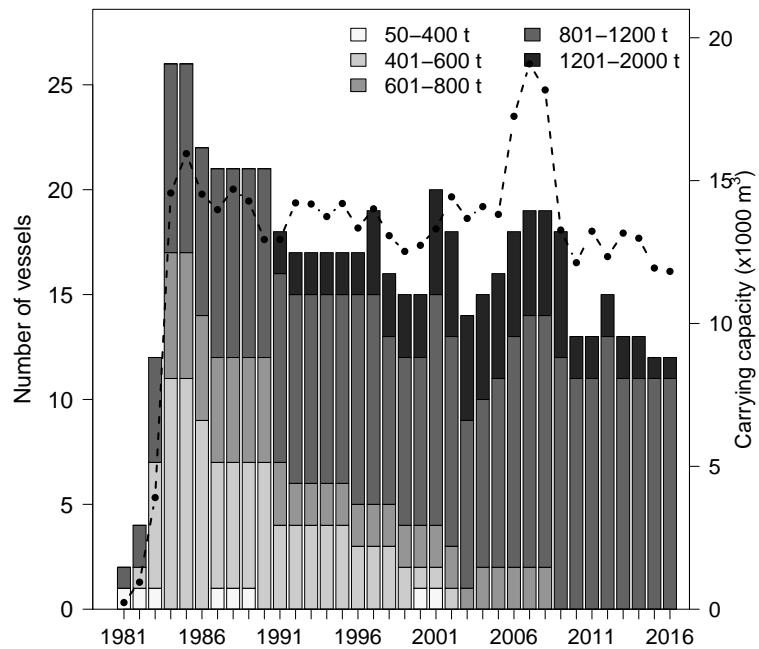

FIGURE 1 – Fishing capacity of the French purse seiner fleet in the Indian Ocean. Annual changes in the number of purse seiners by size category (barplots) and total carrying capacity (solid line with circles) during 1991-2016. Capacity was weighted by the vessel-specific proportion of the year at sea (in months). The vessel size category ( $t$ ) was computed as 0.7 times the capacity expressed in  $m^3$

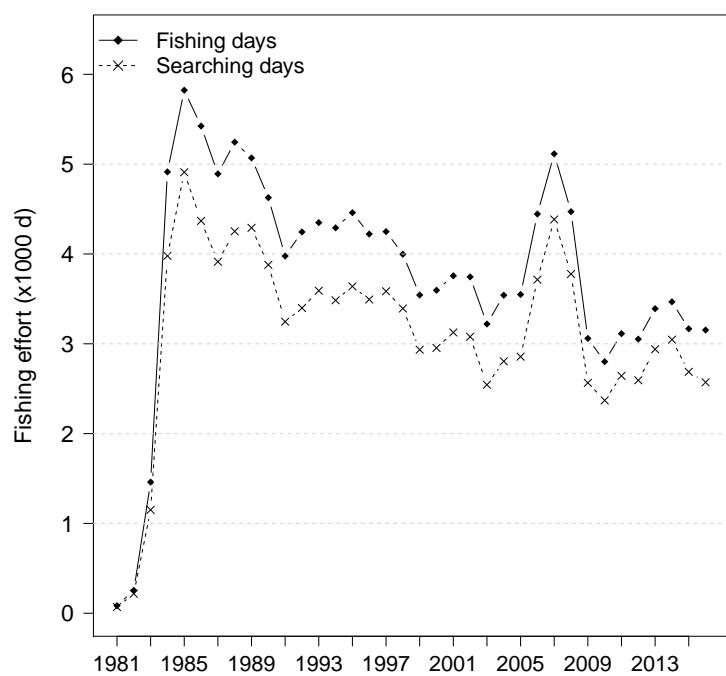

FIGURE 2 – Changes in nominal effort over time. Annual total number of fishing and searching days for the French purse seine fishing fleet in the Indian Ocean during 1991–2016

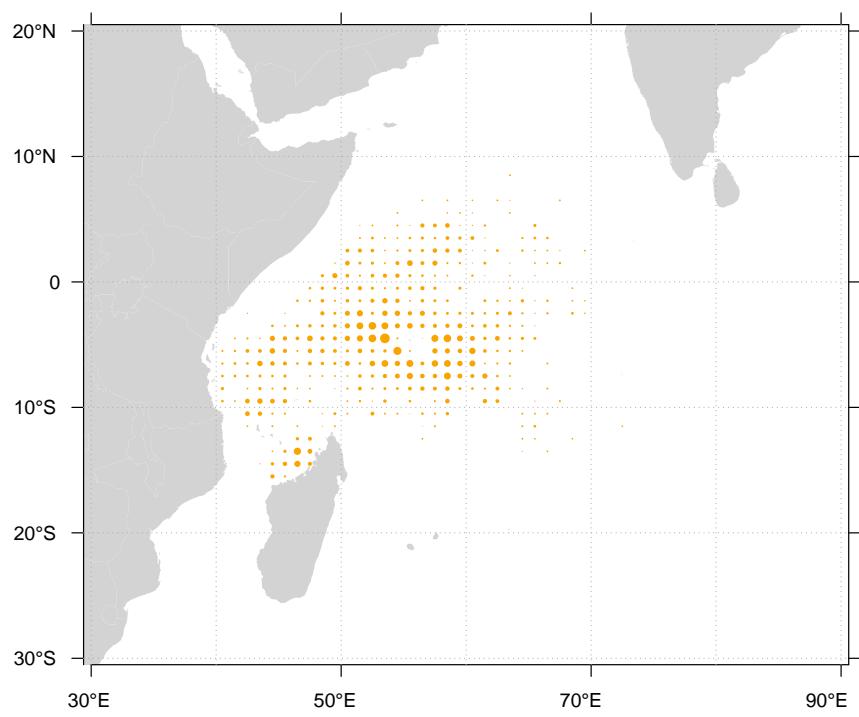

FIGURE 3 – Fishing grounds. Spatial distribution of fishing effort (in searching days) of the French purse seine fishing fleet in 2016

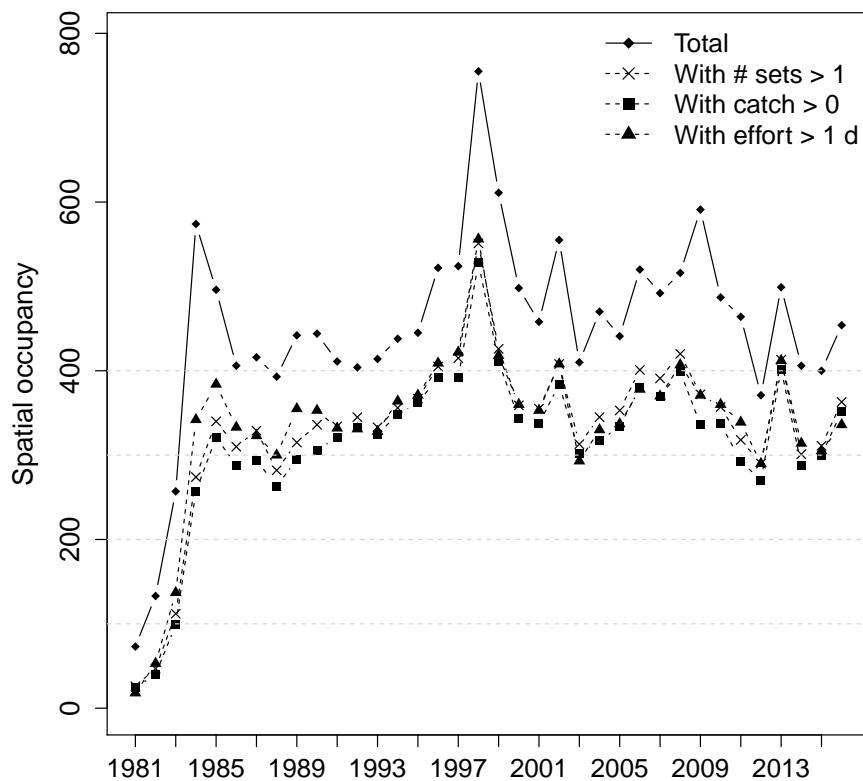

FIGURE 4 – Changes in spatial extent of the fishery over time. Mean annual number of 1-degree squares explored by each vessel of the French purse seine fishing fleet during 1991-2016. Solid line indicates standard deviation. Only vessels in activity during 12 months were selected. A loess function was fitted to the data to illustrate the trend

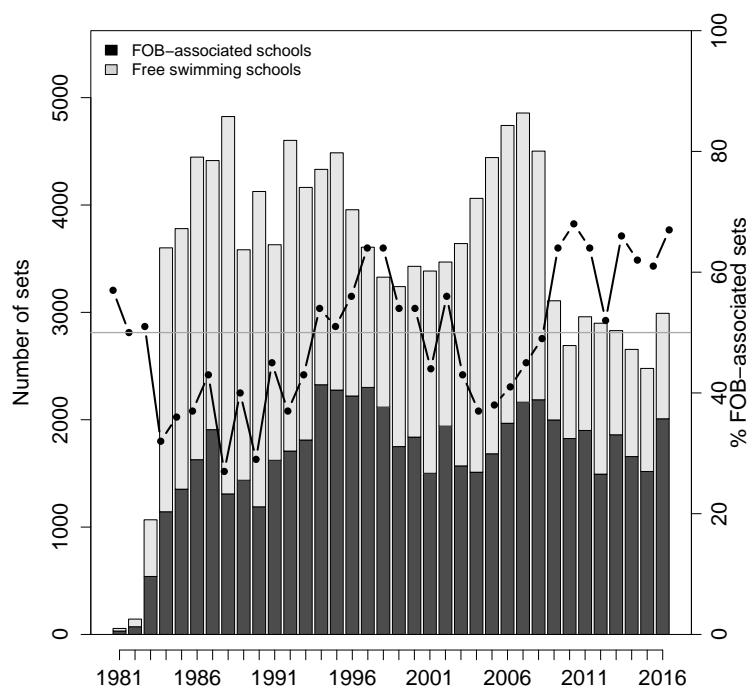

FIGURE 5 – Fishing operations. Annual number of fishing sets in the French purse seine fishery on FOB-associated and free-swimming schools during 1991-2016. Line with solid circles indicates the percentage of sets made on FOB-associated schools over free-swimming schools. Grey solid line indicates the 50% value
