Abstract

Japanese catch data of three pelagic sharks (blue shark, shortfin mako, and porbeagle) and the other sharks between 1964 and 1993 in the IOTC area was updated by using the FAO capture statistics and species composition of the main pelagic sharks calculated from current Japanese observer data. The update was conducted because the IOTC secretariat used unproved species composition of pelagic sharks to estimate Japanese catch data between 1964 and 1993 as the IOTC capture statistics. Japan requests that the IOTC secretariat replace the Japanese annual catches of three pelagic sharks in this period estimated by the IOTC secretariat with the catch data updated in this paper, as the official IOTC capture statistics. Also, the updated catch data of three pelagic sharks can be used in the stock assessments.

Key words

Japanese annual catch; pelagic sharks; the IOTC capture statistics; blue shark; shortfin mako; porbeagle.

Introduction

Japanese annual catches of three pelagic sharks, blue shark (*Prionace glauca*), shortfin mako (*Isurus oxyrinchus*), and porbeagle (*Lamna nasus*) in the IOTC area are currently available at the IOTC website (https://iotc.org/data/datasets) (**Table A1**). At the meeting of 16th working party on ecosystem and bycatch (IOTC, 2020), it was revealed that the Japanese annual catches of the three pelagic sharks between 1964 and 1993 were estimated by the IOTC secretariat based on the FAO capture statistics of sharks (sharks, rays, and skates, etc.) (http://www.fao.org/fishery/geoinfo/en) (**Table A2**) and the species composition of sharks. Since there was no rational evidence of the species composition that the IOTC secretariat used, Japan requested not to use the Japanese catch data for conducting the stock assessment of three pelagic sharks until Japan makes confirmation (IOTC, 2020).

The objectives of this working document paper are to estimate the Japanese annual catches

of the main pelagic sharks (blue shark, shortfin mako, and porbeagle) caught in the IOTC area between 1964 and 1993.

Material and Method

To estimate Japanese annual catches of the main pelagic, Japan used two data sources, the FAO capture statistics and Japanese observer data.

The FAO capture statistics in the IOTC area could be separated into two sub-areas as the western side and eastern side (80 °E based) (http://www.fao.org/figis/geoserver/factsheets/rfbs.html) and there is no information about the species of sharks (**Table A2**). To divide the total shark catches into species-specific catches, Japan followed the procedure as follows; (1) Species-specific catches of the pelagic sharks came from the Japanese observer data was divided into sub-areas, and estimated species compositions of main pelagic sharks (blue shark, shortfin mako, porbeagle, and other sharks) in each sub-area; (2) Japanese annual catches of main pelagic sharks in the subareas were estimated using the FAO capture databases by multiplying the species composition of the main pelagic sharks.

For the total catch of sharks between 1994 and 2020, the FAO capture statistics and the IOTC capture statistics were compared to validate the appropriateness of the total catches of pelagic sharks in the FAO capture statistics prior to 1994. Unlike the Japanese annual total catches until 1993, those after 1993 in the IOTC capture statistics were estimated by Japan based on Japanese logbook data including species-specific catch of the pelagic sharks (Matsumoto *et al.*, 2013).

Results and discussions

The original species composition of the IOTC capture statistics prior to 1994 was 0.53, 0.07, and 0.40 for blue shark, shortfin mako, and porbeagle (**Table A1**). Meanwhile, the species composition of main pelagic sharks calculated from Japanese observer data indicated that the blue shark, shortfin mako, porbeagle, and other sharks accounted for approximately 0.75, 0.04, 0.11, and 0.10, respectively (**Table 1**). The species composition of main pelagic sharks resulted from Japanese observer data is reasonable from the perspective of the productivity and relative biomass of each species (i.e., higher productivity and abundance of blue sharks than those of the other sharks).

The result of estimation of species-specific annual catches based on the species composition come from the observer data was shown in **table 2**.

In addition, with regard to the Japanese annual total catches of pelagic sharks after 1993, the total catches of the FAO capture statistics (http://www.fao.org/fishery/geoinfo/en) (**Table A2**) were smaller than those of the IOTC capture statistics (Matsumoto *et al.*, 2013) (**Table A1**) in each year. The result suggests that the annual total catch for pelagic sharks of the FAO capture statistics prior to 1994 has a possibility to be underestimated.

Conclusions

Japan would like to request that IOTC secretariat should replace the Japanese annual catches of three pelagic sharks (blue shark, shortfin mako, and porbeagle) between 1964 to 1993 with the catch data updated in this paper, as the official IOTC capture statistics. Also, the updated catch data of three pelagic sharks can be used in the stock assessments.
