5 chome 7-1, Orido, Shimizu, 424-8633, Japan

ABSTRACT

In this paper, recent trends of Japanese tuna fisheries in the Indian Ocean up to 2000 are summarized using most recent data available to date (data of 2000 is preliminary). In 1999, Japanese longliners achieved 20% reduction in the number of distant water longline vessel. Total fishing effort (the number of hooks) by Japanese longliners in the Indian Oceans which was about 125 million hooks in 1997 and 1998 decreased to around 100 million in 1999 and 2000 according to the decrease of vessels while the percentages of effort in each Ocean to total has not shown remarkable change. Longline catch for each species in 2000 (1999) was 3,771 (4,956MT) for southern bluefin, 2,406MT (2,324MT) for albacore, 12,511MT (14,105MT) for bigeye and 14,260MT (15,088MT) for yellowfin. In 2000, yellowfin catch was a little larger than that of bigeye as was the recent trend. Regarding to Japanese purse seine fishery, though more than 10 Japanese purse seiners operated in 1991-1993, it decreased year by year to only 2 vessels in 2000. Total fishing effort (operation days + searching days) of purse seine increased from 349 days in 1989 to 2393 days in 1992, and decreased drastically to 320 days in 2000. Nearly 100% of operations were made on the FADs associated school in 2000. Total purse seine catch in weight of each species in 2000 was 2,327MT, 952MT and 747MT for skipjack, yellowfin and bigeye, respectively.

INTRODUCTION

In this paper, recent trend of Japanese tuna fisheries in the Indian Ocean are summarized using most recent data available to date. The fishery statistics used in this paper were provided on the bases of the new IOTC statistical areas, i.e. WEST and EAST Indian Ocean.

In 1999, Japanese longliners achieved 20% reduction in the number of distant water longline vessel. This reduction was significant change in the Japanese longline history and it should be carefully observed whether the reduction of fleet affects on the effort distribution and tuna catch.

LONGLINE FISHERY

The latest available longline data is that of 2000 although the data of this year is preliminary. All catch and effort statistics were made using logbook data.

Fishing vessels

Japanese longline fishery is classified into three categories (coastal, offshore and distant water) according to the license and boat size (coastal: less than 20 gross tonnage (GRT), offshore: 20-120GRT and distant 120-500GRT). Basically, distant water category is allowed to fish in the Indian Ocean. Although some offshore longliners also allowed their operations in this Ocean, there is no operation by them recently. In the latest decade, the number of vessels operated in this Ocean was around 180-250 vessels per year (Table 1), and relatively large in number (224-251) during 1995-1998. In 1999, it decreased to 210 from 239 in 1998. This decrease might be caused by the 20% reduction of Japanese longline fleet.

Fishing Effort

Total fishing effort (the number of hooks) by Japanese longliners (including offshore and distant water longliners) in the Indian Oceans was higher, greater than 100 million hooks between 1983 and 1987and gradually decreased to around 60 million hooks between 1990 and 1993 (Fig. 1). Thereafter, the total effort increased again to about 125 million hooks in 1997 and 1998, and decreased to around 100 million in 1999 and 2000 according to the decrease of vessels. Historically, 20% or less of the total fishing effort was used in the Indian Ocean until 1995 except for 22%-24% in 1983 through 1986 (Fig. 2). After 1997, that percentage exceeded 26% with the peak of 28% in 1999. This recent increase in percentage of fishing effort in the Indian Ocean seems to be attributable to the lower catch of tunas, bigeye tuna in particular, in the eastern Pacific Ocean. Although the total fishing effort decreased in the latest two years as described above, the percentages of effort in each Ocean to total seem not to have changed so much.

Seasonal changes in the distribution of the longline effort in Indian Ocean are shown for 1999 and 2000 (Fig. 3). The seasonal pattern of longline operation has been more or less the same in recent years. In the tropical and sub-tropical Indian Ocean north of 30S, the areas off Mozambique, off Somalia, off Indonesia and off West Australia are main fishing grounds. In these areas, concentrations of fishing effort appeared in the first and forth quarters although the seasonal change is not so clear. In the area south of 30S, effort concentration is observed off South Africa in the second and the third quarters, off southwest Australia in the third quarter. The seasonal changes in the distribution of Japanese logline effort in further south (south of 35S) are

strongly depended on the national regulation (time/area closure and quota) on southern bluefin tuna. That is,

Japanese longliners are allowed to catch southern bluefin from April (or May) to July (or August) in the fishing area off Africa and Tasmania, and from September to the time when their catches fill Japanese quota for this species (normally, November or December).

Catch

Information on catch in weight from 1971 to 2000 caught by Japanese longliners in the Indian Ocean was shown in Table 2 **(Data of 2000 is preliminary)**, and geographical distributions of catch in 1999 and 2000 for major species were shown in Fig. 4 Total catch includes the catch for southern bluefin tuna, albacore, bigeye, yellowfin, swordfish, striped marlin, blue marlin, white marlin, sailfish, shortbill spearfish, and skipjack. Because southern bluefin catch is regulated by quota, and because the catch of southern bluefin tuna in Table 2 is based on aggregated catch data raised from logbook data submitted by longliners including operations targeting on other species, it may be different from actual catch, to some extent. Total catch was kept high during 1983 to 1988 with the highest of about 50,000 MT in 1985. It declined continuously since then to about 19,000 MT in 1991. Total catch increased thereafter as corresponding to the increase in effort and reached to around 40,000-47,000MT in the most recent five years. Catch for each species in 2000 (1999) was 3,771 (4,956MT) for southern bluefin, 2,406MT (2,324MT) for albacore, 12,511MT (14,105MT) for bigeye and 14,260MT (15,088MT) for yellowfin. As pointed out by Matsumoto et al. (2000), the proportion of yellowfin in the total catch has been increasing in recent years, and exceeded that of bigeye in 1999. In 2000 also, yellowfin catch was a little larger than that of bigeye. Matsumoto et al. (2000) suggested that this increase in yellowfin catch proportion was probably due to the decrease of the catch of bigeye and shift of the target to yellowfin since comparatively higher effort of Japanese longline vessels was observed in the western Indian Ocean (from off Mozambique to off South Africa), where CPUE of yellowfin is higher than other waters.

PURSE SEINE FISHERY

The latest available data for Japanese purse seine fishery are those for 2000. The catch and effort data in 2000 can be regarded as the nearly final one.

Fishing vessels

Japanese purse seine vessels in the Indian Ocean are 350-700 GRT class (700-1000 carrying capacity). Historical change in the number of vessel was shown in Table 1. Though more than 10 Japanese purse seiners operated in 1991-1993, it decreased year by year to only 2 vessels in 2000. In these remained two vessels, one is the research vessel of JAMARC (Japan Marine Fishery Resources Research Center). This retreat of Japanese fleet from the Indian Ocean is related to economic reasons (high operating cost, low price of catch, loss in foreign currency exchange).

Fishing Effort

Total fishing effort (operation days + searching days) increased from 349 days in 1989 to 2393 days in 1992, and decreased drastically to 320 days in 2000 (Table 3. Geographical distribution of Japanese purse seine effort in 2000 was shown in Fig. 5. In the fishing area, nearly 100% of operations were made on the FADs associated school.

Catch

Total catch in weight shows a similar trend as that of effort, that is, increased from about 5,000 MT in 1989 to 45,560 MT in 1992, and decreased steeply to 9,308 MT in 1998 (Table 3). Catch in weight of each species in 2000 was 2,327MT, 952MT and 747MT for skipjack, yellowfin and bigeye, respectively
