Rosa Delgado de Molina<sup>1</sup> and Santiago Déniz<sup>3</sup>

**Abstract**

At the present time it is developing, in the Indian ocean, a project in which participate four Spanish boats (two purse seiners and two supplies). It is a pilot project in which participate the shipowners' company ALBACORA S.A. and the Spanish Oceanographic Institute (IEO).

This pilot action mainly aims to make progress in improving the mode of fishing over objects where the impact on stocks of the most sensitive species (bigeye and yellowfin) and the ecosystem (bycatches) is concerned.

To this end, acoustic data will be collected using up-to-date devices (sonar and echosounders) and subsequently analysed to establish criteria that will enable a reduction in catches of juveniles tropical tuna (yellowfin, and essentially, bigeye), based on acoustic selectivity.

At the same time, experiments will be undertaken with several prototypes of artificial floating objects and their behaviour will be studied, to find a typology that will result in fewer bycatches (particularly focussing on the exclusion of accessory catches of turtles) without reducing catches of target species.

Data will be collected for six months, from May to November 2005.

**1. - Pilot Action → Definition**

The Spanish Fishing Administration destines part of its budget to subsidising specific projects called Pilot Actions. Each year a series of these projects covering various fishing issues is presented to the Administration by several shipowners' associations. The Administration chooses and finances the most interesting among them, based on a scientific report from the Spanish Oceanographic Institute.

Participating in this Pilot Action are the following: the Spanish Fishing Administration—through the Secretary General for Maritime Fishing—, the shipowners' company ALBACORA S.A. and the Spanish Oceanographic Institute.

## **2. - Introduction and background**

The Spanish tuna purse-seine fleet operates in intertropical waters in three oceans, with annual catches amounting to around 250,000 t. These catches are obtained in two ways: over artificial floating objects and in free schools. Both sets result in catches of the same species; however, there are differences in specific composition and size, as well as in volume and the number and type of species that constitute the accompanying fauna.

Fishery over free schools or with natural floating objects was traditional until the appearance of fishing over artificial floating objects, which developed from the mid eighties until the early nineties, depending on which ocean. Currently, the catches obtained with either mode of fishing are around 50% (bearing in mind catches from the Atlantic, Indian and East Pacific Oceans). Since the onset of large scale fishing over artificial floating objects the type of object used has not varied substantially (which is not the case for detection systems or the type of localizer borne by the objects). Although the fishery over floating objects has increased purse-seine efficiency and subsequently the catches (particularly of skipjack), the large scale use of objects has had effects on the fishery that were unusual prior to its introduction. On the one hand, catches of numerous accessory species (especially in specific cases and space-time strata) including: sharks, turtles and other fish species (none of which are useful species for purse-seine fisheries); and on the other, the presence and catches of juveniles yellowfin and bigeye tropical tuna (non-target species for this fishery and infrequently caught in free school).

The impact of this mode of fishing on the ecosystem and the exploitation profile generated have meant that fishing over floating objects with boys or FADs has become a cause for concern for the different RFMOs (Regional Fishing Management Organization) responsible for assessing and managing tuna stocks.

The RFMOs have provided recommendations about the need to increase knowledge about this mode of fishing, with a view to assessing its real impact on stocks and to devising appropriate management measures.

## **3. - Objectives**

This pilot action mainly aims to make progress in improving the mode of fishing over objects where the impact on stocks of the most sensitive species (bigeye and yellowfin) and the ecosystem (bycatches) is concerned.

To this end, experiments will be undertaken with several prototypes of artificial floating objects and their behaviour will be studied. The aim is to find a typology that will result in fewer bycatches (particularly focussing on the exclusion of accessory catches of turtles) without reducing catches of target species. At the same time, acoustic data will be collected using up-to-date devices (sonar and echosounders) and subsequently analysed to establish criteria that will enable a reduction in catches of juveniles tropical tuna (yellowfin, and essentially, bigeye), based on acoustic selectivity.

## **4. - Innovations of this Pilot Action**

First-time use of acoustic techniques, aimed at discriminating tropical tuna species and sizes associated with artificial floating objects. The objective of this study is two-fold: a) to examine the aggregation criteria of the different species and sizes and b) to discover school composition prior to the set. Both objectives converge with the final objective,

which is to achieve a reduction in catches of specific species and juveniles specimens that may be suffering overexploitation; in short, to improve purse seine selectivity.

Design and use of new artificial floating objects that are “more respectful” of turtles and other species that group and become entangled in nets hanging from floating objects, while also attempting to maintain the attraction of the tropical tuna that concentrate around them.

## **5. - Geographical area and duration**

Given that the fleet’s most important catches are made in the Indian Ocean, this ocean is then the perfect place to carry out this pilot action. Data will be collected for six months, from May to November 2005.

## **6. - Methodology**

The pilot action will be carried out from two Spanish tuna purse seiners (Albacán and Albacora Quince) and two supplies vessels (Zahara Tres and Taraska).

The vessels used in the experiment will perform different tasks. There are two teams, each composed of a purse seiner and a support vessel. The mission of one of the teams is essentially to collect acoustic data, using the echosounder and sonar installed in the purse seiner and support vessel, and to validate findings with the fisheries undertaken by the purse seiner. The other team will focus on following up objects designed to reduce accidental catches of species, mainly turtles. The catches obtained with “classic” objects will be placed and examined simultaneously in order to confirm the effectiveness of the new objects.

Tasks are separated so as to reduce acoustic data collection to just two vessels, since extensive and complex equipment is required for data storage and treatment. Data collection about the objects can be undertaken by the four vessels involved in the experiment.

The pilot action will be carried out in two three-month stages. After the first stage, the four observers will be changed and the activities may be reconsidered or modified if necessary.

The acoustic devices are those normally used by the vessels since, on principle, the results of this type of scheme must be immediately applied to the fishing sector. The only changes introduced have been to improve data storage to facilitate subsequent treatment.

During trips, the observers collect extensive information about all the vessel’s activities and store information from the echosounder and sonar in precise locations. To this end, they are equipped with a series of forms that can be divided into three groups:

1. Vessel Activity
  - a. Route form and environmental parameters (Figure 1): this will provide us with data for every hour and change of activity for each vessel.
  - b. Fishing and sampling form (Figures 2, 3 and 4): the fishing form gives all information about the set, including catches of tuna and accessory species, in addition to discards.
2. Objects

- a. Form containing the characteristics of traditional and experimental objects (Figure 5): this form is for collecting information about each object when it is deployed, visited or fished.
3. Acoustic Data
- a. Echosounder data form (Figure 6): used to note down the data for each sounder recording.
  - b. Sonar data form (Figure 7): used to note down the data for each sonar recording.

Each vessel has a different protocol for collecting general data and acoustic sampling data, depending on whether the team is dedicated to acoustic data collection or not and to whether it is a purse seiner or support vessel.
