

# Preparation of data input files for the assessments of Indian Ocean yellowfin tuna stock

Miguel Herrera<sup>1</sup>, Julien Million<sup>2</sup> (IOTC Secretariat)

#### Summary

This document describes the methods used by the IOTC Secretariat to prepare catch, effort tagging data and length-frequency tables for the assessments of the Indian Ocean yellowfin tuna stock, for the period 1950-2010, using estimates of total catch and the available catch-and-effort, size frequency data and other biological data in the IOTC database.

Using information from the IOTC database, the IOTC Secretariat prepared a flat table containing estimates of total catches, and the effort and length-frequency samples available, by fishery, assessment area, year and quarter.

The results are affected by the lack of information for some fleets, areas and years, and, in particular, by the lack of catch, effort and size data from most artisanal fleets and some industrial fleets.

#### Rationale

The IOTC database contains estimates of total catches by country, gear, year and IOTC Area (**Figure 1**). In addition, the IOTC database contains catch-and-effort data and size frequency data by country, gear, time-area strata and species, which generally represent a sample of the total catches estimated by country, gear, year and species.

The Secretariat used the above data to produce an input file containing estimates of total catches of yellowfin tuna, in number and weight, and the effort and length-frequency samples available by fishery, assessment area, year and quarter. This file was used for the assessments of yellowfin tuna, carried out using Multifan-CL (MF-CL), Stock Synthesis III (SS3), or other assessment models. The results of the assessments are reported in separate papers<sup>3</sup>.

The IOTC is hosting the database developed under the framework of the Regional Tuna Tagging Project in the Indian Ocean (RTTP-IO). This database contains all the information on releases and recoveries of yellowfin tuna, bigeye tuna and skipjack tuna tagged by the RTTP-IO. Tagging information from other tagging projects (*e.g.* past project in Maldives, and small-scale project of the Indian Ocean Tuna Tagging Programme) is also available but was not used for the assessments. The Secretariat prepared a file containing releases and recaptures of yellowfin tuna, to be used for the assessments.

#### Input Table

The Secretariat prepared a table containing the following information for the assessments of yellowfin tuna:

- a. Total catches of yellowfin tuna, in number of specimens and weight, by year, quarter, assessment fishery (Table 6), and assessment area (Table 7 and Figure 2).
- b. Effort data by year, quarter, assessment fishery, and assessment area, including:
  - a. Industrial purse seine and longline fleets: Estimates of total effort by stratum (i.e. fishery, area, year and quarter) in strata for which effort data were available (no effort was estimated in strata for which no effort data were available at all)
  - b. Other fleets: The effort data were used as available.
- c. Number of yellowfin tuna specimens **sampled** by **length** interval, year, quarter, assessment fishery, and assessment area.
- d. Number of yellowfin tuna **tagged and release** by length, region of release and quarter (*i.e.* release event), and for each release event, the number of recovered yellowfin by length at release and by fishery of recovery (tagging data).

Examples of the input table can be found in Appendix I.

<sup>&</sup>lt;sup>2</sup> Fishery Officer, IOTC Secretariat ( jm@iotc.org; Julien.Million@iotc.org )

<sup>&</sup>lt;sup>5</sup> Preliminary stock assessment of yellowfin tuna in the Indian Ocean using MULTIFAN-CL, A.Langley *et al.* (IOTC-2011-WPTT13-36) and Stock assessment by Stock Synthesis III (SS3) for yellowfin tuna in the Indian Ocean, T. Kitakado *et al.* (IOTC-2011-WPTT13-37)

#### **Basic Data**

Five datasets are used for the preparation of the input files for the assessments of yellowfin tuna:

- <u>Nominal catches</u>: Total catch estimates per Species, Fleet, Year, Gear and IOTC Area (**Figure 1**). The data in this dataset issues from two different sources:
  - a. Reports from the flag countries or reports from other countries on the catches of foreign vessels operating within its Economic Exclusive Zone or based in ports within its territory.
  - b. Estimates carried out by the IOTC Secretariat: this may involve changes in the catches reported by the above or the estimation of catches for non-reporting fleets (e.g. catches recorded under the NEI<sup>4</sup> category), using various sources.

- <u>Catch-and-effort by area</u> (derived from the catch-and-effort table): Catches by species (in tonnes or/and in number of fish) and effort are recorded by Fleet, Year, Gear, Fishing Mode, Time Interval (month or quarter usually) and area (usually 1<sup>°</sup> square areas for industrial purse seine fisheries, 5<sup>°</sup> square areas for industrial longline fisheries and various regular or irregular areas for artisanal fisheries). Catches/effort by area are not available for all Nominal catches strata. When recorded, the catches/effort in these datasets might represent the total catches/effort of the species in the year for the fleet and gear concerned or represent simply a sample of those.
- <u>Size data</u>: Size frequency data (standard or processed lengths or standard or processed weights) are recorded by Species, Fleet, Year, Gear, Fishing Mode, Time Interval (month or quarter or year usually) and area (usually 5<sup>°</sup> square areas for purse seine fisheries, 10<sup>°</sup> latitude by 20<sup>°</sup> longitude for longline fisheries and various regular or irregular areas for artisanal fisheries). Size data are not available for all Nominal catches strata. When recorded, the size data might represent the total catches of the species in the strata concerned (Catch-at-Size) or simply a sample of those (non-raised or partially raised samples).
- *Biological data*: includes several types of biological parameters for the yellowfin tuna, in particular:
  - a. <u>Conversion from non-standard measurements into fork length</u>: Equations (data) used to convert specimens of yellowfin tuna measured by using non-standard procedures into the standard length measurement used for these species, representing the distance from the tip of the snout to the fork of the tail (fork length).
  - b. <u>Conversion from fork length into live weight</u>: Equations (data) used to estimate sample weights from the available lengths (length-weight relationships).
- <u>Tagging data</u>:
  - a. <u>Release data</u>: number of release at length, quarter and region of release. In total during the RTTP-IO, 54,688 yellowfin were released in the western Indian Ocean.
  - b. <u>Recovery data</u>: 9,612 tagged yellowfin were recovered and reported as of December 2010 (??). Most of the recoveries are reported from the purse-seine fleet at the moment of the unloading of the fishing vessel in the ports of the Indian Ocean, in particular Seychelles. For all these recoveries, the information collected contains no specific date and location of recapture but the date of recovery (*i.e.* unloading) and the well number in which the tagged fish was recovered. This information is then linked with the logbook database of the fleet in order to extract the need information about the location, date of recapture and type of association.
  - c. <u>Recovery data</u>:

<sup>4</sup> Not elsewhere identified

The type of information recorded in each case is summarized in Table 1 below:

Table 1: Ma	in types of fisheries statistics gathered by the IOTC			
Dataset	Fishery Strata	Time Period Strata	Area Strata	Represents
Nominal Catches	Fleet-Gear type (or gear aggregate)-Species (or species aggregate)	Year	IOTC Area (Western / Eastern Indian Ocean)	Total catches
Catch- and-Effort	Fleet-Gear (or gear aggregate)-Fishing Mode (purse seine only)-Species	Month (quarter or year)	1° square area (purse seine) 5° square area (longline) Other regular or irregular areas	Sample
Size frequency	Species- Fleet-Gear (or gear aggregate)-Fishing Mode (purse seine only)-Type of measurement (length or weight, standard or processed)-Size interval (between size classes)	Month (quarter or year)	5° square area (purse seine) 10° Lat.x20° Lon. area (longline) Other regular or irregular areas	Sample
Biological data	Various, depending on dataset	Various	Various, depending on dataset	Sample
Release data	Species, length, gear	Date of release	Position of tagging	Total
Recovery data	Species, length or weight, gear	Date of recovery (or estimation)	Position of recovery (or estimation)	Total

#### Data Processing

Summary of the estimation procedures used in the preparation of input files for the assessments of yellowfin tuna

#### Catch, effort and length frequency samples file:

- 1. Standardizing catch, effort, and size frequency tables
  - a. Nominal catches (NC): Assigning the catches not reported by species/gear by species/gear (NC→NCst)
  - b. Catch-and-effort (CE): Assigning catches/effort not recorded by quarter by quarter (CE→CEst)
  - c. Size frequency (SF $\rightarrow$ LFst):
    - i. Converting non-standard measurements into standard measurements
    - ii. Breaking the existing lengths into the standard length class intervals used for the species
    - iii. Scaling down length frequency distributions to sampled numbers
      - 1. EC purse seiners: scaling down CAS to the numbers of fish estimated for sampled purse seine sets
      - 2. Other fleets: scaling down CAS or raised length distributions to the actual numbers of fish sampled, where required
    - iv. Assigning length samples by quarter
- 2. Assigning catches, effort and length samples by year, quarter, fishery and assessment area (NCst/CEst/LFst → NCELfa):
  - a. Fleets operating fully within one of the yellowfin tuna assessment areas (artisanal fleets): Assigning total catches (NCst) and available effort (CEst) and length samples (LFst) by fishery, assessment area, year and quarter (NCst/CEst/LFst → NCELfa<sub>1</sub>)
  - b. Fleets operating in two or more assessment areas (industrial fleets):
    - i. Breaking CEst by fishery,  $5^{\circ}$  grid, year and quarter (CEst  $\rightarrow$  CEds)
    - ii. Breaking NCst by fishery, 5° grid, year and quarter using the CEds (NCst → NCds)
    - iii. Assigning LFst by fishery, 5° grid, year and quarter (LFst→LFds)
    - iv. Assigning total catches (NCds) by fishery, assessment area, year and quarter (NCds → NCELfa<sub>2</sub>)
    - v. Estimating total effort (CEds) by fishery, assessment area, year and quarter for industrial purse seine and longline fleets (CEds → NCELfa<sub>2</sub>) in strata where effort data are available
    - vi. Assigning the available length frequency samples (LFds) by fishery, assessment area, year and quarter for other fleets (LFds  $\rightarrow$  NCELfa<sub>2</sub>)
  - c. Merging NCELfa1 and NCELfa2 into NCELfa

Yellowfin tuna MF-CL input file (NCELfa →NCEL<sub>MFCL</sub>): re-allocating strata from NCELfa into other assessment areas. The catches (in weight<sup>5</sup>), effort, and length data for some fisheries were reallocated to specific areas when the accumulated catches in the area concerned represented a small proportion of the total catches for the fishery concerned.

#### Release and recapture data file:

- 1. Assigning releases by length, year, quarter and assessment area (i.e. release event)
- Assigning recaptures by release event, year and quarter of recapture, fishery and assessment area 2.
  - Assigning date and location to the recoveries on-board purse-seiners:
    - i. Linking date of recovery (i.e. unloading) and well number with the logbook database
    - ii. Assigning possible sets from which the recapture might come from
- Deriving reference catches: Deriving catches of yellowfin tuna for vessel trips sampled for tags, by gear, fishing mode, and 3. quarter.

#### Standardizing catch, effort and size frequency tables

#### i. Estimating total catches of yellowfin tuna by fleet, gear, year and IOTC Area

The catches in the IOTC nominal catches database are not recorded by species and/or by gear in all cases. The Secretariat conducted a review aiming at estimating catches when data were not available by species or gear in the IOTC database. This process was documented in a paper presented to the WPTT in 2004 (IOTC-2004-WPTT-06). The disaggregation of catches does not affect significantly the catches of yellowfin tuna.

#### ii. Standardizing the available catch-and-effort data

The catches in the catch-and-effort table are recorded under different levels of aggregation. All the catches from this record were assigned by Species-Fleet-Gear-Fishing Mode-Year-Month-5° square grid-Catch in number of fish-(and/or)-Catch in metric tons.

- i. Converting from non-standard effort units into standard effort units: The effort units reported vary depending on the fleet and/or fishing period. The units of effort that were selected by fishery are shown in Table 2 (page 4). In some cases, especially for some artisanal fisheries, the units of effort reported were assumed to be equivalent to the standard units of effort selected for those fisheries.
- ii. It is important to note that the effort recorded for industrial purse seine fisheries has not been broken down by fishing mode (LS and FS) as the actual effort exerted on free schools or associated schools is unknown. Thus, the effort recorded under FS and LS actually represents the effort exerted by industrial purse seiners as a whole, not the effort for the individual fisheries.

Table 2: Sta	ndard length, first length, interval a	nd total number of size classes used for the yellowfin tuna
Fishery	Standard Effort Units	Other effort Units considered to be the same as the standard effort unit
LS	Number of days fishing (FDAYS)	
FS	Number of days fishing (FDAYS)	
LL	Number of hooks set (HOOKS)	
LF	Number of hooks set (HOOKS)	
BB	Number of trips (TRIPS)	Number of fishing days (FDAYS), number of days at sea (DAYS)
GI	Number of trips (TRIPS)	Number of fishing days (FDAYS), number of days at sea (DAYS)
HD	Number of trips (TRIPS)	Number of fishing days (FDAYS), number of days at sea (DAYS)
TR	Number of trips (TRIPS)	Number of fishing days (FDAYS), number of days at sea (DAYS)
OT	Number of trips (TRIPS)	Number of fishing days (FDAYS), number of days at sea (DAYS)
NOTE: Refer	to Table 6 for a description of the fisher	ies referred to above

- iii. Area allocation: All the catches/effort not recorded by 5° square areas were assigned to 5° square areas as follows:
  - a. Allocation of catches/effort recorded under irregular areas to regular grids: The catches/effort recorded under irregular areas (e.g. port of unloading, fishing district, etc.) were assigned to the neighbouring regular grids.
  - b. Allocation of catches/effort recorded under areas that fell within a single 5° square area: all catches/effort recorded under areas that fell within a 5° square area were assigned to the corresponding 5° square areas.
  - c. Allocation of catches/effort recorded under areas overlapping two or more 5° square areas: all catches/effort recorded under areas that overlapped two or more 5° square areas were assigned proportionally by 5° square areas (i.e. by using the proportions obtained by dividing the amount of 1 degree square grids that fell within each  $5^{\circ}$  square area over the total amount of squares from the overlapping area).

<sup>&</sup>lt;sup>5</sup> Note that while numbers of yellowfin tuna were used in previous assessments the present assessment uses catches in metric tonnes

- v. <u>Time period allocation</u>: The catches/effort available in the catch-and-effort file were assigned by month as follows:
  - a. Allocation of catches/effort recorded under time period strata that fall within a single month: all catches/effort recorded under time periods that fell within a month were assigned to the corresponding months.
  - b. Allocation of catches/effort recorded under time period strata overlapping two or more months: all catches/effort recorded under time periods that overlapped two or more months were assigned proportionally by month (e.g. 1/3 of the catches/effort recorded under the first quarter of a year were assigned to each of the months making up that quarter).

#### iii. Standardizing the available size frequency data

The following process was used to convert the samples available for the yellowfin tuna into standard form:

- i. <u>Converting from non-standard measurement types into standard length</u> (**Table 3**): The regression equations presented in **Table 3** were used to estimate the distance from the tip of the snout to the fork of the tail (fork length) for specimens of yellowfin tuna that were recorded under non-standard lengths or weights in the IOTC database:
  - a. Conversions from gilled-and-gutted weight into fork length: The conversion from gilled-and-gutted weight into fork length was done by using a distribution matrix for the yellowfin tuna, estimated by using individual weight (GGT)-length (FL) measurements.
  - b. Other measurements: any other non-standard measurements were converted into fork length by using the equations on **Table 3** (deterministic conversion).

#### Table 3: Yellowfin tuna: Regression equations used to convert from non-standard measurements into standard lengths

	-						-	
Type Measurement	Equation	Parameters	Sample size	Size range	Variance	Covariance ab	Mean Residual	Gradient
Weight gilled and gutted <sup>A</sup>	$aW^{b}$	a= 44.28699 b= 0.3008591	2,361	Min:14 Max:71	a=0.00752476509 b=2.86244E-07	-4.626246E-05	4.095958	a=3.033852 b=495.6385
Length to the base of the 1 <sup>st</sup> dorsal fin <sup>B</sup>	$aL^{\flat}$	a=2.0759 b=1.1513	7,036	Min: 29 Max: 164				
Length base of first dorsal fin to fork of caudal fin				Ν	o equation available			
A: Data from IPTP Penang So B: Data from the Indian Ocea	ampling P	rogramme (1992 c. F. et al in IOT	-93) C-2006-W	(PTT-09)				

- ii. <u>Breaking the samples by the standard length frequency intervals used for the yellowfin tuna</u>: The length-frequency interval that is used for the yellowfin tuna is shown in **Table 4** (page 5).
  - a. Allocation of specimens recorded under length classes that fall within a single standard length class:
    - Yellowfin tuna specimens recorded under one centimetre length classes were aggregated under the corresponding length classes (e.g. specimens of yellowfin tuna recorded under the classes 16-17cm and 17-18cm were accumulated under fork length 16cm<sup>6</sup>).
    - Yellowfin tuna specimens recorded under two centimetre length classes that fell within standard length classes were assigned to the corresponding standard length classes (e.g. specimens recorded under length class 16-18cm were assigned to fork length 16cm)

Table 4: Standard lengt yellowfin tuna	th, first length, ir	nterval an	d total number o	f size classes ı	used for the
	Stan I and	First	Interval	Total	Maximum
Species	Jan eth *	length	between length	number of	interval allowed
	Length	(cm)	classes (cm)	size classes	(cm)
Yellowfin tuna	Fork length	10	2	150	4
NOTE: All samples in the recorded under length in	IOTC database wer tervals greater tha	e assigned n the maxi	according to the sp mum interval speci	pecifications ab fied above wer	ove; the samples e not used
*Refers to the straight dis	stance measured, to	o the closes	st lower centimetre	, between the t	ip of the snout
(upper-jaw) and the fork	of the tail (FL)				

b. Allocation of specimens recorded under length classes overlapping two or more standard length classes: all the specimens recorded under length classes that overlap the standard classes used for the species (Table 2) were assigned proportionally to the corresponding standard length classes (e.g. 1/3 of the yellowfin tuna specimens recorded under length class 17-20cm were assigned to length 18cm, and 2/3 to length 18cm). All samples containing specimens of yellowfin tuna recorded under length intervals 5cm or higher were discarded.

<sup>&</sup>lt;sup>6</sup> Note that lengths are recorded to the lowest length interval, e.g. the length range of specimens recorded under length 16cm for a species for which 2cm intervals are used is 16cm(inclusive)-18cm(exclusive); note that medium values are used to estimate weights from the available lengths (17cm in this case).

- iii. <u>Weighting length frequency distributions to sample numbers</u>: The length frequency data in the IOTC database do not represent sample numbers in all cases as some countries report length frequency data that has been raised in various ways (e.g. to the catches in the stratum covered through sampling, to the total catches estimated for the country, etc.).
  - a. EC purse seiners: The EC reports length frequency distributions for EC purse seiners that have been raised to the total catches of each 5° square grid and month; the CAS for each stratum were weighted by the numbers of fish estimated for the sampling units making up the stratum (which is the catches corresponding to all sets within fish compartments where samples were taken).
  - b. The actual sample numbers were used for all other fleets to weight the reported length frequencies, when required; i.e. the number of specimens recorded under each length class was multiplied by the number obtained by dividing the total number of specimens sampled (all lengths combined) by the total number of specimens in the raised length frequency (all lengths combined).
- iv. <u>Time period allocation</u>: The available length frequency samples were assigned by quarter as follows:
  - a. Allocation of specimens recorded under time-periods that fall within a single quarter: all specimens from samples recorded under time periods that fell within a quarter were assigned to the corresponding quarter.
  - b. Allocation of specimens recorded under time-periods overlapping two or more quarters: all specimens from samples recorded under time-periods that overlapped two or more quarters were assigned proportionally by quarter (e.g. 2/3 of the specimens recorded under the time period February-April of any year were assigned to the first quarter (Jan-Mar) of that year while the remaining 1/3 specimens were assigned to the second quarter (Apr-Jun)).
- v. <u>Estimation of sample weights</u>: Weights by sample were calculated by adding the weights estimated for all the specimens making it. The equations used to estimate weights from the available lengths are shown in **Table 5** (note that deterministic methods were used for the conversion).

Table 5: Ye	llowfin tuna: Equ	ations used to convert from standard (fork) length	into round weight,	by species

#### Assigning catches, effort and length samples by year, quarter, fishery and assessment area

#### i. Allocation of assessment fishery:

Each Fleet-gear stratum in the length frequency data table was assigned to the corresponding assessment fishery. Details on the fleet-gear length frequency strata making up each fishery are shown in **Appendix III**. **Table 6** shows the fisheries that are used for the assessment of yellowfin tuna. It shows also total catches by fishery accumulated for the entire catch data series (1950-2009) and the contribution that the catches from each fishery made to the total accumulated catches for 1950-2009, and in recent years (2005-09).

Table 6: accumu	Fisheries used for the assessments of Indian Ocean yellov lated for the period 1950-2009 (Total Catch 50-09) and the	vfin tuna; the tota e relative importa	l catches nce of eacl	n fishery
over bo	th the entire catch series (%50-09) and in current years (%	605-09) is also sho	wn	
Fishery	Description	Total Catch 50-10 (,000 t)	% 50-10	% 06-10
FS	Industrial purse seines on free-swimming schools	1,905	19	17
LS	Industrial purse seines on associated schools (FAD)	1,435	14	17
LL	Industrial longlines (freezing vessels)	2,527	25	12
LF	Industrial longlines (fresh-tuna vessels)	877	9	8

GI	Gillnets	1,747	17	26
HD	Hand lines	653	6	8
TR	Troll lines	512	5	6
OT	Other artisanal gears	46	1	1

#### ii. Allocation of assessment area

The total catches, effort and samples existing for the yellowfin tuna were aggregated by assessment area. The areas that were used for the assessments of the yellowfin tuna stock are shown in **Table 7** and **Figure 2**. The catches of yellowfin tuna from areas outside the five areas were assigned to the closest area, as indicated through the arrows on **Figure 2**. **Table 7** shows also total catches by area accumulated for the entire catch data series (1950-2010) and the contribution that the catches from each area made out of the total accumulated catches for 1950-2010, and in recent years (2006-10).

Table 7: Areas used for the assessments of Indian Ocean yellowfin tuna; the total catches (tonnes) accumulated for the period 1950-2010 (Total Catch 50-10), the relative importance of the catches in each area over both the entire catch series (%50-10) and in current years (%06-10), and the accumulated 1950-2010 catches by assessment fishery (Table 6, page 9) in each of the areas concerned are also shown

		Catch	%	%			Catches	by Fishery	1950-20	010 ( ,000	0 t)		
Area	Description	(,000 t) 50-10	50- 10	06- 10	FS	LS	LL	LF	BB	GI	HD	TR	ОТ
1	Arabian Sea	1,987	20	23	54	67	449	12	44	871	517	39	35
2	Western IO	4,662	46	42	1701	1202	1095	3	390	7	33	44	1
3	Southwest IO	874	9	10	102	128	345	2	2		47	271	1
4	Southern IO	106	1	0			103	8	<1	<1	<1	21	<1
5	Eastern IO	2,516	25	26	48	38	536	852	8	869	56	136	9

Note that the catches from areas that were kept for the assessment are shown in bold; the catches from other areas (*italics*) were allocated to one of the areas selected for the assessment, depending on the fishery (refer to Table 8 on page 8 for details)

The following process was used to allocate the existing samples by area:

- i. <u>Allocation of catches, effort and length samples available for selected fisheries to specific assessment areas</u>: The catches, effort and samples available for selected fisheries were fully assigned to specific assessment areas on the assumption that the majority of the specimens caught by those fisheries comes from the areas selected. This is thought to be the case with the majority of artisanal fisheries and with a limited number of industrial fisheries. Details on fleet-gear size frequency strata that make up each area are shown in **Appendix II**.
- ii. <u>Allocation of the catches, effort and length samples available for other fisheries</u>:
  - a. Breaking the nominal catches by time-period and area: the nominal catches for the fisheries concerned were assigned by month and 5° square areas by using the catches by time period and 5° square grids available for the yellowfin tuna (see "*Standardizing the available catch-and-effort data*" on page 3). The following process was used:
    - a. Nominal catches strata for which time-area catches exist:
      - i. Deleting strata from the CE table: The CE for NEI-(deep)-freezing longliners and NEI-fresh tuna longliners were not used because they refer to very specific areas and time-periods and are not considered to be representative of the activities of these fleets.
      - ii. Breaking the nominal catches by time and area: The nominal catches were broken by time and area in years for which spatio-temporal catches were available for the fleet concerned.

- b. Nominal catches strata for which CE data do not exist:
  - i. Catches per area are available for the same fleet in years before or after the year concerned:

- 1. Catches for the same species are available: The catches recorded in the five years closest to the year of reference were accumulated and the average values obtained used to break the catches per area in the year concerned. Data extending to up to 25 years above or below the year concerned are used.
- 2. Catches for other species are available:
  - a. The catches recorded in the year of reference were accumulated and the average values obtained used to break the catches per area in the year concerned
  - b. The catches recorded in the five years closest to the year of reference were accumulated and the average values obtained used to break the catches per area in the year concerned. Data extending to up to 25 years above or below the year concerned are used.
- ii. Catches per area are not available for the same fleet in years before or after the year concerned or they are available but very far in time (more than 25 years before or after the year concerned): The catches available for other fleets (and years) are used to break the nominal catches per month and  $5^{\circ}$  square area/s.
  - 1. Catches per area for the alternative fleet are available for the same year: This information is used to break the nominal catches per time and area.
  - 2. Catches per area for the alternative fleet are not available for the same year: The same substitution scheme as the one defined in ii.a. above is used.
- b. Estimation of total effort for industrial purse seine and longline fleets: The efforts recorded for industrial fleets were raised to represent the total catches of the fleet concerned, where required.
- c. Allocation of catches, effort and length samples recorded under areas that fall within a single assessment area: all catches, effort and length samples recorded under areas that fell within one of the areas used for the assessment (Figure 2) were assigned to the corresponding assessment area. It is important to note that all catch and effort data falls under this category (see a. above and "Standardizing the available catch-and-effort data" on page 3).
- d. Estimation of total effort for longline and purse seine fisheries: The effort of longline and purse seine fleets for which no effort data were available was estimated using the catches for those fleets and catch rates from fleets for which effort data were available. No effort was estimated in strata in which effort data were not available from any fleet.
- e. Allocation of length samples recorded under areas overlapping two or more assessment areas: all specimens from samples recorded under areas that overlapped two or more assessment areas were assigned by assessment area using the proportion that the catches in the area within each assessment area made out of the total catches concerned (e.g. if the samples overlapped areas 2 and 3 and the catches in the area sampled were 1t for area 2 and 2t for area 3, 1/3 of the fish sampled by length class was assigned to area 2 and 2/3 to area 3).

The resulting data were aggregated to obtain total catches (in weight), and effort and length samples by year, quarter, assessment fishery, and assessment area.

# It is important to note that no weighting procedure was used when aggregating the available length samples by assessment fishery and area.

#### Putting together the input file for the assessments of yellowfin tuna with MF-CL

The catches (in number and weight), effort and length frequency samples from some fisheries in some areas were reallocated to other areas, especially in cases where the catches represented a small proportion of the total catches for the fishery concerned and where no tag releases had been recorded for those fisheries and areas. Overall, around 3% of the catches of yellowfin tuna were re-allocated to other areas. The catches in italics in **Table 7** (page 6) represent the catches that were re-allocated to other areas for each fishery. The criteria used for the allocation of catches are shown on **Table 8**.

Table 8: Areas used for the assessments of the Indian Ocean yellowfin tuna stock: criteria used for the re-allocation of catches, effort and length samples from the areas where they were recorded to the areas used for the MF-CL assessment. The proportion of catches from each fishery that were re-allocated to other area/s, over the total catches for that same fishery for the entire time series (1950-2009), is also shown % of Area 1 Area 2 Area 3 Area 4 Area 5 Areas used Fishery catches re-(MFCL assessment) Catch, effort, length frequency data re-allocated to Area allocated FS 2, 3, 5 2 2 3 5 2.8 LS 2 3 2, 3, 5 2 5 4.7

OT	1, 5	1	1	1	5	5	4.0

After the re-allocation process, the catches (in weight), effort and length frequency samples were aggregated by Fishery, Assessment Area, year, and quarter. An example of the Input Table that was built for the assessments of yellowfin tuna with MF-CL can be found in **Appendix I**.

#### Assigning releases by year, quarter and assessment area (*i.e.* release event)

In 2011, the Secretariat included in the database all the tagging data generated during the pilot and small-scale projects implemented during the Indian Ocean Tuna Tagging Programme. This includes releases in Maldives, India, Indonesia, Mayotte as well as releases in the eastern and south west Indian Ocean, made by other institutions with the support of IOTC. During the preparation of the tagging data, all the releases and recoveries from these projects have also been included.

Year and quarter of release are derived from the exact date of release. All the recoveries are then assigned in each of the assessment area described in figure 2. Yellowfin were released during 10 quarters from May 2005 to September 2007 in region 1(3169 releases), 2 (56521 releases), 3 (707 releases), 4 (2 releases) and 5 (2182 releases).

Assigning recaptures by release event, year and quarter of recapture, fishery and assessment area

#### i. Assigning date and location to the recoveries:

- i. <u>Linking date of recovery (*i.e.* unloading) and well number with the logbook database:</u> recoveries made during fishing can be assigned with a precise date and location of recapture. However, a large proportion of the recoveries were made on-board the purse-seine fleet at the moment of the unloading. For these, the information provided is the date of recovery (*i.e.* unloading) and the well, and a link has to be made with the logbook of the purse-seiner in order to be able to assign a date and position of recapture.
  - i. Assigning possible sets from which the recapture might come from: the editing of the data is done for each tag one by one through a "data editor" software that was designed to link the recovery database with the logbook database. The software extract from the logbook the data for each set that was loaded into the well where the fish was recovered.
  - Assigning possible sets from which the recapture might come from: in the case of only one set was loaded in the said well, the date and position of the recovery will be the one assigned for this set. However, most of the time, sets were mixed and therefore the date and position will be an average of the different dates and positions.

#### Putting together release and recovery data of yellowfin tuna

Different files are produced for the users of the tagging data, however, the main client file is includes **all** the individual information for the releases and the recoveries, including the estimation of the position for the recoveries on-board the purse-seine fleet.

#### Reporting Rates, Shedding Rates and Reference Catch

In addition to the tagging data (releases and recoveries), it is important that the users are provided with additional sets of data including Reporting Rates, Shedding Rates and the Reference Catch:

<u>Reporting Rates:</u> out of the recapture tagged not all are reported to the IOTC Secretariat. In order to fully account for the tagged fish that have been recaptured and not reported, it is necessary to assess the Reporting Rates. Estimating reporting rates was done by IOTC for the European purse-seine fleet based in Seychelles through on-board observer and the cooperation of skippers.

Shedding Rates: shedding rates accounts for the number of tags that fell of the fish after tagging and are assessed through double tagging. A shedding rate analysis was done in 2008 and updated in 2009.

Reference Catch: reporting rates estimated for the purse-seine fleet do not apply to the totality of the catch unloaded by the fleet, but only to the proportion of the catch that is unloaded in Seychelles. This proportion were assessed by the scientists of the EU in order to be incorporated in the final analysis of the tagging data.

#### Main issues relating with the preparation of data for the assessments of YFT with MF-CL

#### i. Estimates of total catches

- i. <u>Catches in weight</u>: The presumed quality of the time-area catches of yellowfin tuna estimated for the MF-CL assessment is shown in **Figure 3**. The quality of the catches estimated for the yellowfin tuna is thought to be fair to good for industrial fisheries (both purse seine and longline) and, since 1970, for the baitboat fishery. The time-area catches estimated for the remaining artisanal fisheries (gillnet, hand and troll lines and other artisanal fisheries) are thought to be compromised due to:
  - a. Uncertain estimates of total catches due to missing or insufficient data collection and/or processing systems in some countries (Yemen, Comoros, Madagascar)
  - b. Catches by quarter and/or fishing area not available (Iran, Sri Lanka, Pakistan, India, Indonesia)
  - c. Uncertain estimates of catches by fishery: catches by gear not available, affecting especially handline and trolling fisheries

#### Figure 3: Proportion of time-area catches of yellowfin tuna that are not available, by fishery and year

ii. <u>Catches in number</u>: The numbers of yellowfin tuna caught are derived by using the catches in weight estimated by fishery, quarter and area and average weights estimated from the catch-at-size data for the same strata. Therefore, the estimation of numbers caught is compromised by the lack of samples for some fisheries, areas and periods (**Figure 4**, page 9), especially artisanal fisheries and the longline fishery of Japan in recent years.

#### ii. Quality of effort data

The quality of the effort data by fishery and time-area strata is compromised due to the following reasons:

- i. <u>Effort data not available</u>: Effort data are not available from many fisheries, especially artisanal fisheries; and fresh-tuna longline fisheries during some periods. In addition, the effort available for industrial purse seiners cannot be broken by fishery; thus, the effort recorded for free-schools and associated-schools is the same, representing the total effort of the purse seine fleets in each case.
- ii. <u>Use of different units of effort for a same fishery</u>: number of fishing trips, number of days-at-sea and number of fishing hours has been indistinctly used as effort units for some artisanal fisheries. In general, it was assumed that, in the case of artisanal fisheries all were equivalent as all days at sea are generally fishing days and trips are usually one day long. However, this assumption needs to be confirmed for some artisanal fleets, for which there is grounds to believe that the fishing grounds exploited and trip durations may have been extended in recent years (gillnet fisheries of Iran, Sri Lanka and Pakistan and Maldivian pole-and-line fishery)
- iii. <u>Uneven coverage of effort among the fleets making up a fishery</u>: The effort recorded for a particular fleet may represent the total effort exerted for that fleet or simply a sample of it. In addition, effort coverage levels may be different depending on the fleet, period or area concerned. Thus, the effort recorded for a fishery and time-area strata may be incomplete and effort coverage levels may be uneven throughout the data series. The effort in the MF-CL table represents simply the effort sampled for the artisanal fleets for which there is effort available. On the contrary, the effort for industrial fleets was raised to represent the total catches of the fleet concerned and, subsequently, the total catches from all fleets making up the longline fishery, for quarters in which effort data were available.

#### iii. Quality of length frequency samples

**Figure 4** shows the proportion that the numbers of yellowfin tuna sampled (or raised to the sampling unit) made out of the total numbers of yellowfin tuna caught, by fishery, year and area. The quality of the length frequency samples by fishery and time-area strata is compromised due to the following reasons:

- i. Length frequency samples are not available for some fisheries and periods, including:
  - a. Trolling fisheries from area 2 and area 3: length samples are not available at all throughout the entire catch series.
  - b. All Handline, Baitboat and Gillnet fisheries and Trolling and Other fisheries from areas 1 and 5: length samples are only available for some periods, representing a very small proportion of the catches in most cases.
  - c. Purse seine and longline fisheries for some areas and periods
- ii. <u>Number of fish sampled unknown</u>: The length frequency data available for European, Seychelles and assimilated purse seiners refer to the total number of fish in the sampling units that were sampled, not representing the actual sample numbers, as it is the case with all other fleets. The amount of fish that is actually sampled for purse seiners may range between 4-20% of the number

recorded in the length samples, depending on the proportion of specimens of small size or large size within the sampling units. In addition, the length frequency data available for the Sri Lankan fisheries in some periods had been raised to the catches in the stratum, not representing the actual sample numbers. The number of fish sampled was estimated by dividing the number of fish recorded under each length class by the minimum interval obtained between consecutive length classes for the samples concerned.

Figure 4: Yellowfin tuna: availability of length frequency samples, by fishery, area, and year.
Industrial purse seine fisheries (FS; LS): Proportion that the total number of yellowfin tuna estimated in sampling units having been sampled made out of the total numbers of yellowfin tuna caught

• Other fisheries (LL; BB; GI; HD; TR; OT): Proportion that the total number of yellowfin tuna sampled made out of the total numbers of yellowfin tuna caught

iii. <u>Uneven coverage of length samples among the fleets making up a fishery</u>: The length samples recorded for a fishery represent simply the lengths from the fleets for which samples are available while the amount of fleets from which samples are available and the sample coverage levels may have changed depending on the fleet or time-area covered. This is believed to be a problem in the following cases:

- a. <u>Longline fisheries</u>: the contribution that the samples from the different fleets has made to the length frequency distributions derived for the longline fishery has changed significantly over the time-series:
  - i. 1952 to 1979: Length samples were only available from Japanese longliners, even though longliners from Taiwan, China operated through the majority of this period (since 1954)
  - ii. 1980 to mid-1990's: Length samples available from Japan and Taiwan, China; changing numbers of specimens covered through sampling over the total number of specimens caught for this period, depending on the fleet; Taiwan, China tends to catch yellowfin tuna specimens of smaller size than those caught by Japan.
  - iii. Mid-1990's to date: Length samples are available from other fleets; the amount of specimens sampled by Japan decreased considerably during this period; large number of yellowfin tuna specimens measured for the fresh-tuna longline fisheries of Indonesia and Taiwan, China (OFCF sampling); Taiwan, China tends to catch yellowfin tuna specimens of smaller size than those caught by Japan.
- b. Gillnet, handline and trolling fisheries: Length samples are only available from selected fleets and periods.

iv. <u>Representativeness of the size samples</u> of yellowfin tuna taken on longliners of Japan and Taiwan, China:

- a. Commercial longline fisheries of Japan and Taiwan, China: During the WPTT in 2010 the IOTC Secretariat presented preliminary results of a review carried out to compare average weights estimated for tropical tunas, as derived from the time-area catches and size samples available in the IOTC database for the longline fisheries of Taiwan, China and Japan. The results showed conflicting average weights derived from the two sources for all species and for most time-area strata. These discrepancies may originate on catch-and-effort or size data not representative of the fisheries concerned; or poor estimation of total catch by species. The reasons for these discrepancies need to be further explored.
- b. Japanese training and research longline vessels: In recent years the majority of the samples available for the longline fishery of Japan come from training vessels. The representativeness of the samples collected on training vessels is uncertain, as these vessels do not necessarily operate the same areas or use the same fishing techniques as the commercial vessels from Japan and tend to catch yellowfin tuna of larger length (cf. IOTC-2010-WPTT-08).

v. <u>Length samples referring to areas that overlap to or more assessment areas</u>: The majority of the samples available for the longline fishery are recorded by quarter and 10 degrees latitude by 20 degrees longitude areas<sup>7</sup>. This means that a significant amount of samples overlaps two or more assessment areas, samples that need to be allocated by assessment area.

In consequence, the length distributions that are derived for the above fisheries and periods are not considered to be representative of those fisheries as a whole.

#### iv. Quality of release data

There is no major problem identified in the quality of the release data from the RTTP-IO. Reliability codes were used to qualifying the data quality, *e.g.* quality of the tagging or of the tagged fish. For instance the values attained by some of these codes are as follows:

- i. Some doubt on the species identified for only 1.04% of all tuna tagged; among these fish there are 579 Unknown species (unknown) accounting for 0.34%;
- ii. 1.14% of the Fork Length are not completely reliable including 1,368 with no FL accounting for 0.81%;
- iii. 2.43% of the fish are not released in a very "good" condition, *e.g.* 1,052 dropped on deck or having hit the vessel accounting for 0.63%.

There is probably more quality issues with the release data from the pilot and small-scale operations due to the nature of these projects. However, this data has not yet be fully analysed.

#### v. Quality of recovery data

The quality of the recovery data is completely dependent on the recovery platform and one the awareness campaign that were designed and implemented. In fact, recoveries of artisanal fleet for example, are in general of a lower quality. By being host in Seychelles, based of the major tuna purse-seine fleet of the Indian Ocean, the RTTP-IO was able to design and implement a large and comprehensive tag recovery strategy in Seychelles, ensuring good quality of the recoveries. However, as the majority of the recoveries were made by the stevedores during the unloading and the transhipment of the fishing vessel, part of the recovery information had to be estimated from the logbooks, *i.e.* data and position of the recapture, type of association of the school (*e.g.* free or log school).

In the 10560 recoveries of yellowfin tuna, there are 891 for which no position of recoveries could be assigned (542 from purseseine). One of the main issues regarding the quality of the recoveries of the purse-seine fleet is that for a large proportion of them, the type of school association is unknown, while they are defined separated fisheries in the model, *i.e.* for 34% of the recoveries, the association type is not known.

Table 10: Number of yellowfinrecoveries from industrial purse seinersby fishing mode		
Fishing mode	Nb	
Free-swimming schools	1253	
Associated schools	4840	
Unknown fishing mode 3144		

To include these recoveries in the model, they had to be distributed among the free school and log school recoveries, keep the proportion of each type for each year.

#### Main changes in the preparation of data with respect to previous MF-CL assessments

There have not been important changes in the preparation of data for the assessments of yellowfin tuna, other than:

i.

- ii. Breaking of longline fisheries, recorded as a single fishery in previous assessments, into freezing longline and fresh-tuna longline fisheries, with all catch, effort and length data for fresh-tuna longline fisheries assigned to Area 5. The reason for this is that fresh-tuna longliners have traditionally operated in tropical waters of the eastern Indian Ocean, the main fleets operating Indonesia or Taiwan, China flags. The separation of longline fisheries into freezing longline (LL) and fresh-tuna longline (LF) also allowed for a more precise estimation of total effort for the freezing longline component, as effort data are more complete in this case.
- iii. <u>Correction in the recovery data:</u> in order to better estimate the real number of tag recapture, the recoveries from the purse-seiner where separated in at-sea recoveries (recoveries made during fishing) and on-land recoveries (recoveries made during the unloading/transhipment in Seychelles), and for each the number of recoveries with an unknown set type were distributed in the free and log school type. Moreover, the recoveries on-land were corrected by the reporting rate estimated through the tag seeding experiment that took place on-board the purse-seine fleet based in Seychelles and with the proportion of the catch of the purse-seine fleet that was unloaded in Seychelles.

<sup>&</sup>lt;sup>7</sup> Note that the standards of reporting existing at the IOTC for size data from longline fisheries are month and 5 degrees square grid

# Proposal for additional work to be undertaken in relation with the preparation of datasets for future assessments

The fisheries defined for the MF-CL assessment are made in some cases of a high number of fleets and gears (Appendix III). The catches and samples recorded under some fisheries may, for this reason, combine specimens of different size, depending on the fleet or time-period involved and the amount of data that are available over the time series from each fleet. In addition, the representativeness of some sets of catch-and-effort and/or size data may be compromised due to poor sampling coverage or for other reasons. A more thorough analysis of the information at hand is required in order to be able to select the fisheries and areas that represent best the yellowfin tuna fishery and the fleets that made up each fishery and area.

The following changes are suggested in the preparation of data for future assessments of yellowfin tuna with MF-CL, provided that the above analysis is undertaken:

- i. <u>Weighting all length frequency distributions by the actual sample numbers</u>: The length frequency distributions for purse seiners represent the total number of specimens within the sampling units selected while the length frequency distributions for other fleets represent the actual sample numbers; initially the length frequency distributions for purse seiners could be weighted by the real sample numbers in each stratum. However, the actual number of lengths measured on industrial purse seiners is not known for all fleets and time-area strata.
- ii. <u>Weighting the existing length samples by fleet prior to the aggregation of samples under each fishery</u>: The length distributions in the MF-CL were built by aggregating the length samples for the fleets under each fishery, irrespective of the sampling coverage levels for the fleets involved; in some cases, the estimation of length distributions could be improved by weighting the lengths sampled by fleet prior to the aggregation of lengths for the fleets making up a fishery. However, the little amount of size data that are available from some fisheries, in particular coastal fisheries, may compromise the weighting of samples for those and needs to be further explored.
- iii. <u>Improving the estimation of the total number of recaptured tags</u>: the process on how to distribute the unknown set type recoveries and how to adjust for the reporting rate need to be better discussed and formalized for all the analysis.

Year	The year where the catches were made
Quarter	The quarter where the catches were made (Jan-Mar(1), Apr-Jun(2), Jul-Sep(3), Oct-
	Dec(4))
FisheryCode	Type of fishery (FS; LS; LL; LF; GI; HD; TR; OT)
Assessment Area	The areas used for the assessment (1; 2; 3; 4; 5)
Catch	Total catch estimated (in metric tonnes of fish)
Effort	Fishing effort estimated (longline and purse seine fisheries) or available (other
	fisheries)
C001C150	Number of yellowfin tuna measured (sampled) by length class, using 10cm as the first
	class(lower bound) and 2cm intervals
C001	Number of YFT specimens having a fork length between 10cm and 12cm
C002	Number of YFT specimens having a fork length between 12cm and 14cm
	And so forth
